

Eat-resume

Product: eat-resume (AI-Powered Resume Screening Pipeline)

1. The Problem Statement

In modern talent acquisition, the top-of-the-funnel is broken. For every open corporate requisition, companies receive an average of 250+ applications. Hiring managers and recruiters are forced to manually screen these documents, spending an average of 3 minutes per resume to determine basic role alignment.

The Core Problem: Highly-paid HR professionals and departmental leaders are wasting hundreds of hours on low-level data parsing and keyword hunting. This manual bottleneck leads to recruiter burnout, extended Time-to-Hire (TTH), and the loss of top-tier candidates to faster competitors.

2. Target Personas

The problem acutely affects two primary users within an organization:

Persona A: "Sarah," The High-Volume Corporate Recruiter

- **Role:** Senior Talent Acquisition Specialist
- **JTBD (Job-to-be-Done):** Filter the noise to present a shortlist of highly qualified candidates to the hiring manager.
- **Pain Points:** * Overwhelmed by "spam" applicants who apply to every open role.
 - Suffers from "resume fatigue," increasing the likelihood of human error or unconscious bias at the end of a long day.
 - Frustrated by traditional ATS systems that only look for exact keyword matches, forcing her to manually read resumes anyway.

Persona B: "David," The Busy Hiring Manager

- **Role:** Director of Product / Engineering / Sales
- **JTBD (Job-to-be-Done):** Quickly evaluate if a candidate has the specific hard skills and contextual experience needed for his team.
- **Pain Points:** * Resents the time hiring takes away from his primary job (building products/driving revenue).

- Needs specific gap analysis (e.g., "Does this PM have *B2B SaaS* experience, or just general PM experience?"), which standard filters cannot provide.
-

3. The Status Quo & The "Cost of Doing Nothing"

Currently, companies handle top-of-funnel volume in one of two ways:

1. **The Brute Force Method:** Humans manually read every resume. **Cost:** At 250 resumes × 3 minutes = 12.5 hours of manual reading per job posting. For a company hiring 50 roles a year, this equates to over 600 hours of wasted productivity.
2. **The Keyword Filter Method:** Using legacy Applicant Tracking Systems (ATS) to automatically reject resumes missing specific words. **Cost:** High rate of "false negatives." Candidates who use different terminology (e.g., "Client Success" instead of "Account Management") are unfairly rejected, while unqualified candidates who "keyword stuff" their resumes slip through.

4. Market Research Summary

An analysis of the current HR Tech landscape reveals a massive gap between legacy software capabilities and modern GenAI potential.

- **Legacy ATS Platforms (Workday, Taleo, older versions of Greenhouse/Lever): ***
Capability: Excellent at workflow tracking and compliance.
 - *Weakness:* Their "screening" relies almost entirely on Boolean search strings and exact keyword matching. They cannot understand *context* (e.g., they don't know that "managed a \$5M P&L" implies "strong leadership").
- **Emerging AI Screening Tools (Eightfold.ai, Fetcher):**
 - *Capability:* Advanced talent matching and sourcing.
 - *Weakness:* Often heavily enterprise-focused, requiring massive data lakes to train models, multi-month onboarding, and six-figure contracts. They are inaccessible to mid-market agile teams who just need immediate, contextual resume evaluation.
- **The Candidate Behavior Shift:** The market has shifted. Candidates are increasingly using AI (like ChatGPT) to mass-apply to jobs and perfectly tailor their resumes to beat legacy ATS bots. The volume of "looks good on paper" resumes has skyrocketed.

5. The "eat-resume" Opportunity

Why Now? The advent of highly capable, affordable Large Language Models (like Google Gemini 2.5 Pro) makes contextual reasoning instantly accessible.

eat-resume fills the gap in the market by offering an agile, contextual pipeline. Instead of relying on rigid keywords, *eat-resume* uses AI to conceptually "read" the candidate's experience, evaluate it against the nuance of a specific Job Description, and automate the routing (Interview/Hold/Reject) and email drafting.

The Result: We shift the recruiter's job from *data parsing* to *human connection*, effectively reducing a 12-hour manual task to a 15-second automated loop.
